

# Towards better understanding of **synthesis- morphology-performance in polyamide membranes:**

Visualization under controlled reaction conditions

**Adi Ben Zvi<sup>1,2</sup>, Guy Z. Ramon<sup>1,2</sup>**

*1 Civil & Environmental Engineering, Technion – Israel Institute of Technology*

*2 Nano-science and Nano-Technology program, Technion – Israel Institute of Technology*

The diagram illustrates the interfacial polymerization (IP) reaction. On the left, a porous polymeric support (gray) is shown with a layer of **M-phenylene diamine (MPD)** (Nc1ccc(N)cc1) adsorbed on its surface. Above the support, a solution of **Trimesoyl-chloride (TMC)** (ClC(=O)c1cc(C(=O)Cl)cc1C(=O)Cl) is present. An orange arrow labeled **IP reaction** points to the right, where a **Polyamide film** (orange) is formed on the support surface. A pink box highlights the reaction conditions:

- A very **fast** reaction  $< 1$  sec.
- A **thin** ( $< 250$  nm) PA selective

Chemical structures for the reactants are shown: TMC (top) and MPD (bottom).

- A very **fast** reaction  $<1$  sec.
- A **thin** ( $<250\text{nm}$ ) PA selective layer

**IP reaction**

## Random motion (Brownian)

Trajectories:

Isotropic motion

- No bulk flow.
- The motion is thermal-driven.

## Directed motion

Trajectories

Evidence for instability

Anisotropic motion

- Particles act as tracers that move with the bulk.
- **Brownian + bulk directed motion**

# Conclusions

Synthesis	Increasing <b>monomer concentrations</b>	Adding a <b>co-solvent</b>	Adding a <b>surfactant</b>
Instability	More directed motion	More directed motion	Below CMC - More directed motion  Above CMC – 'Brownian like' motion
Morphology	More crumpled morphology	More crumpled morphology	Muti-layered morphology

Tracking particles provides us with new insights about IP
